Improving forest structure monitoring with GEDI

Live aboveground woody biomass

Maps were produced by Ty Wilson and Doug Griffith (barrywilson@fs.fed.us, dgriffith@fs.fed.us). Tile layers produced by Bryan Hemmer (bhemmer@fs.fed.us).

Northwest Forest Plan Effectiveness Monitoring

Changes in older forest

Young forest

Old forest

Causes of those changes

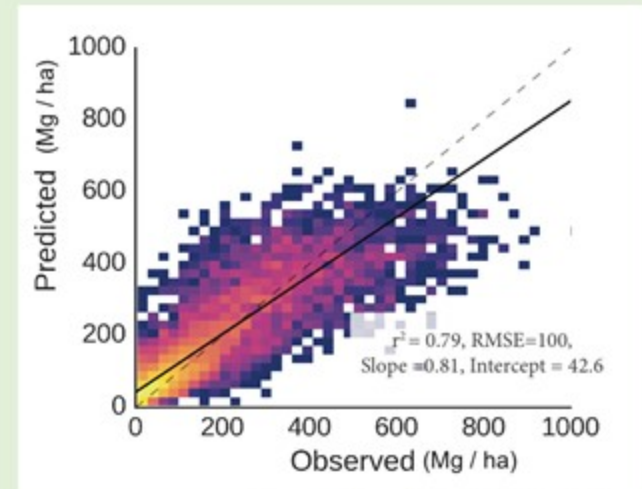

Timber harvesting

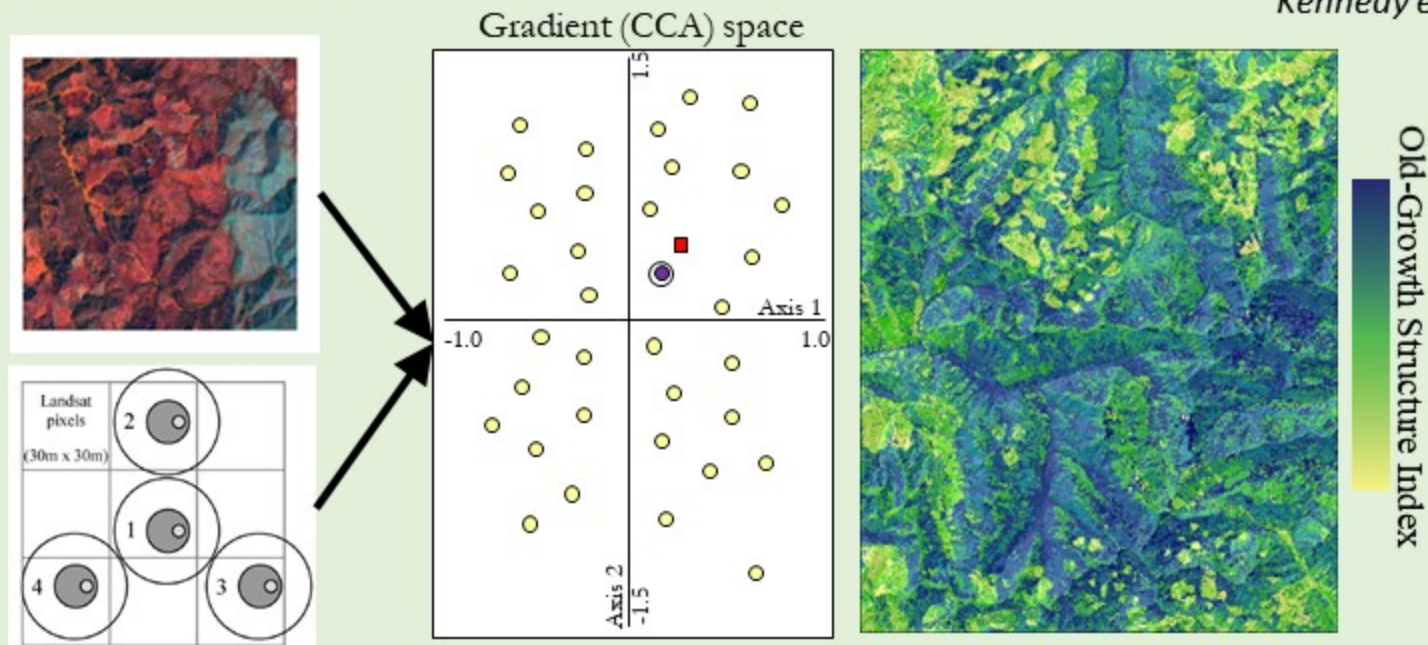

Wildfire

Nearest neighbor approach to vegetation mapping

- Flexible method for integrating remote sensing and forest inventory
- Spectral saturation makes mapping of old-growth forest structure with optical remote sensing challenging

Kennedy et al. 2018. ERL

Improving maps with remotely sensed height

- Incorporating remote sensing of height (e.g., lidar) into NN mapping improves accuracy (Zald et al. 2014. RSE)
- However, wall-to-wall lidar at regional scales is not available

Landsat only

Aerial image

Landsat + lidar

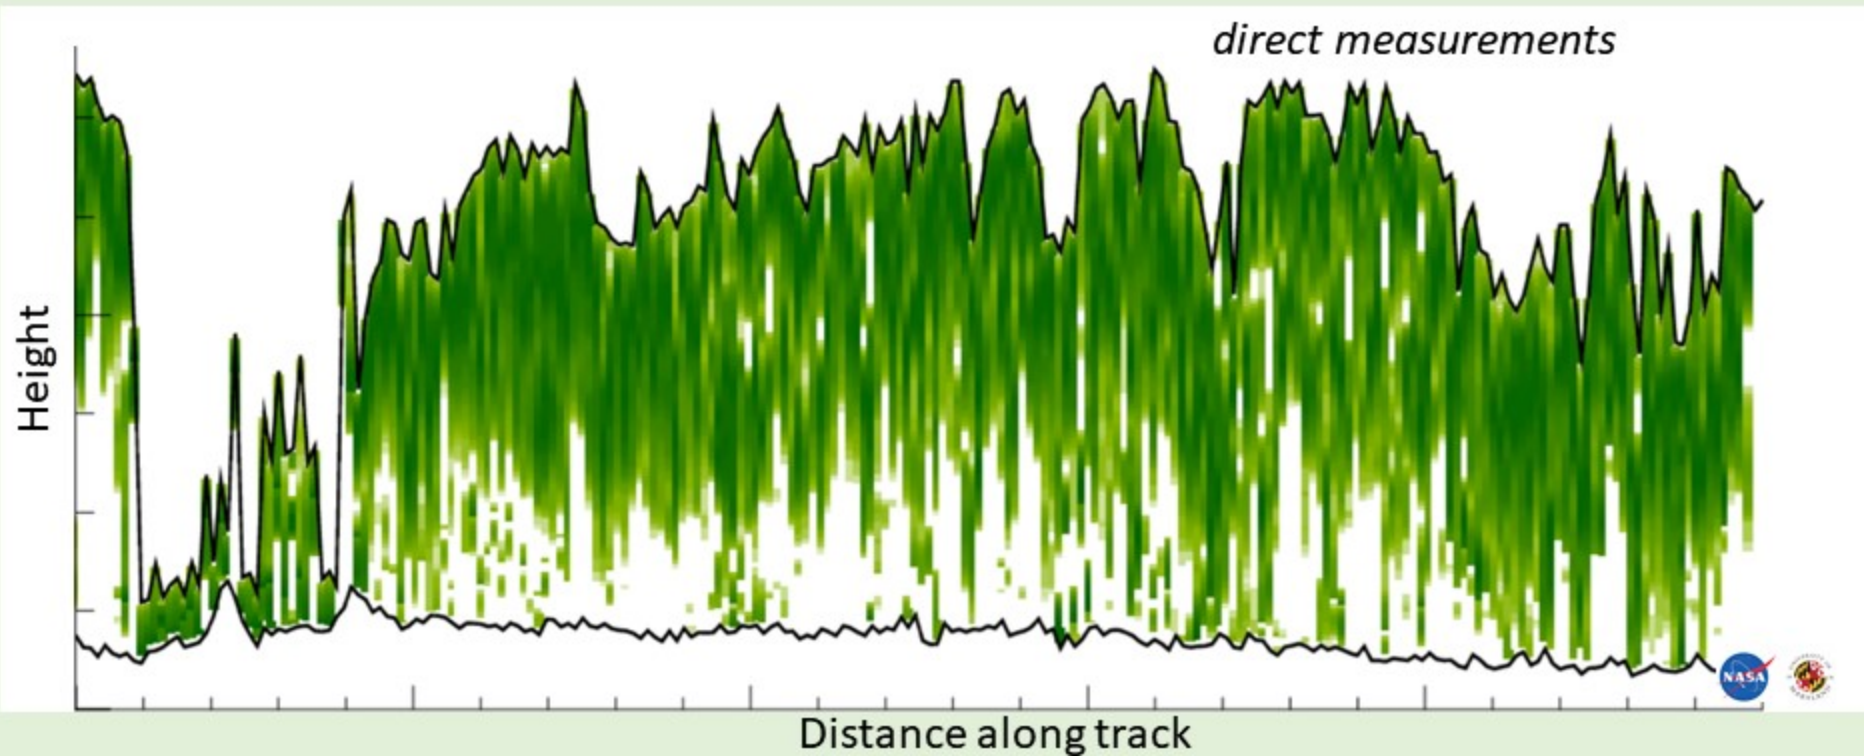

Mapping the old growth structure index

- Represents forest succession (young to old)
- Density of large live trees
- Live tree size class distribution
- Dead wood components

The GEDI measurements

- Forest canopy height
- Canopy vertical structure
- Surface elevation

OBI-WAN

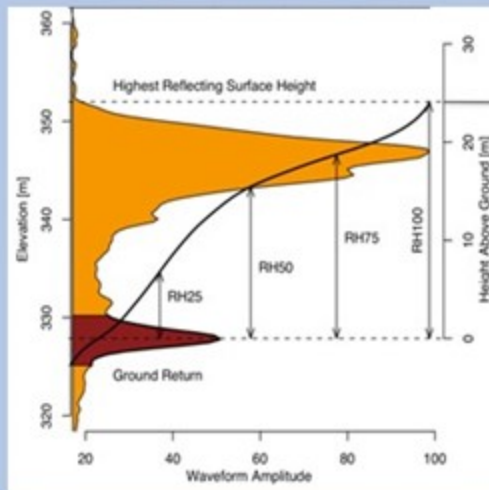

- OBIWAN is an application for making customized GEDI-based carbon estimates
- It links GEDI shots to ancillary data (entire Landsat and Sentinel-1&2 archives, for example) through Google Earth Engine
- We could use the same platform and ancillary data to model forest structure from GEDI across the entire Pacific NW

Make Structure Model

Apply model to image time series

Modeled structure time series

Improving old-growth forest structure mapping

- Improved wall-to-wall inputs = improved maps
- Quantify the improvement with validation data from FIA plots
- Support regional monitoring and planning efforts
- Increase capacity to address complexity and scope of forest policy issues (climate change, sustainability, etc.)

Thank You!
